Stored Procedures

- User-created functions that are stored in the database just like other schema elements
- Procedure vs. Function
  - A procedure does not return any value, while a function does
  - In PostgreSQL, a procedure is simply a function that returns void

Example: Hello World

```sql
create function hello() returns void as $$
begin
  raise notice 'Hello world in PL/pgSQL';
end;
$$ language plpgsql;
```

Example: Add10

```sql
create function add10( a integer ) returns integer as $$
declare
  b   integer;
begin
  b := 10;
  return a + b;
end;
$$ language plpgsql;
```

Procedural Language (PL)

- A programming language for writing stored procedures
- Usually based on some existing language like SQL, Java, C#, Perl, Python ...
  - E.g. PL/SQL, PL/Java, PL/Perl ...

Why Use Stored Procedures?

- Performance
  - Compiled and optimized code
  - Save communication overhead
- Security
  - Access control
  - Less data transferred over the wire
- Simplify application code
- Triggers for data integrity
Why Not To Use Stored Procedures?

- Portability
- PL are generally more difficult to develop and maintain than conventional programming languages
  - Less language features
  - Less tool support

PostgreSQL PL/pgSQL

- SQL + things you would expect from a conventional programming language:
  - Variables and types
  - Control flow statements
  - Functions

Elements of a Programming Language

- Comments
- Literals
- Variables and Types
- Operators and expressions
- Statements
  - Special statements, e.g. input and output
- Functions
- Classes
- Packages

Elements of PL/pgSQL

<table>
<thead>
<tr>
<th>Comments</th>
<th>Literals</th>
</tr>
</thead>
<tbody>
<tr>
<td>Same as in SQL</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Variables and types</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mostly the same as in SQL, with a few special types and operators</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Operators and expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>Functions</td>
</tr>
<tr>
<td>Classes</td>
</tr>
<tr>
<td>Packages</td>
</tr>
<tr>
<td>Not supported</td>
</tr>
</tbody>
</table>

Basic Function Syntax

CREATE [OR REPLACE] FUNCTION name ( parameters )
RETURNS type AS $$
DECLARE
declarations
BEGIN
  statements
END;
$$ LANGUAGE plpgsql;

DROP FUNCTION name ( argtype[,...]);

Examples: Basics

- Implement a function that takes two integer parameters and displays the sum
Basic Syntax and Output

- Variable declaration
- The assignment operator :=
- RAISE
  - Levels: DEBUG, LOG, INFO, NOTICE, WARNING, EXCEPTION
  - Format output with %

Examples: Statements

- Implement a function that returns the name of a student given the student’s id
- Implement a function that calculates factorial

Naming Conventions

- We want to avoid using the same names for variables and table columns
- A simple naming convention:
  - Prefix parameters with p_
  - Prefix local variable with l_
  - Prefix package global variable with g_

SELECT...INTO

```sql
SELECT select_list INTO variable_list
FROM table_list
[WHERE condition]
[ORDER BY order_list];
```

- SELECT result must be a single row.

Branch Statement

```sql
IF condition1 THEN
  statements1
ELSIF condition2 THEN
  statements2
ELSE
  statements3
END IF;
```

- NOTE: don’t forget the semicolon (;) after END IF.

Loop Statements

```sql
LOOP
  statements
  WHILE condition LOOP statements
  END LOOP;
```

```sql
FOR loop_variable IN [REVERSE]
  lower_bound..upper_bound LOOP statements
END LOOP;
```
Examples: Types

- Implement a function that randomly returns two student records

Special Types

- %TYPE
- %ROWTYPE
- Each table defines a type
- SetOf
- Cursor

Cursor

- An iterator for a collection of records
- We can use a cursor to process the rows returned by a SELECT statement

Using Cursors

- Declaration
- OPEN
- FETCH
- CLOSE

Cursor - Open

- OPEN cursor FOR query
- The query is executed
- The position of the cursor is before the first row of the query results

Cursor - Fetch

- FETCH cursor INTO target
- Move the cursor to the next row
- Return the row
Cursor - Fetch

- FETCH cursor INTO target
- Move the cursor to the next row
- Return the row

If there is no next row
- target is set to NULL(s)
- A special variable FOUND is set to false

Cursor - Close

- CLOSE cursor;

Query FOR Loop

FOR target IN query LOOP
    statements
END LOOP;

Examples: Cursor and Query For Loop

- Implement a function that randomly select 20% of the students
  - Using cursor
  - Using query for loop

About PL Programming

- It's just programming like you always do
- Debug code one small piece at a time
- Ask "How to do X" questions in the class forum
- Avoid re-implementing SQL
  - For example, to compute max(price), use SELECT MAX(price) instead of using a cursor to iterate through all rows
Triggers

- Procedures that are automatically invoked when data is changed, e.g. INSERT, DELETE, and UPDATE.
- Common use of triggers
  - Enforcing data integrity constraints
  - Auditing
  - Replication

Trigger Example

Create a trigger that audit the changes to the grades in the enrollment table

```sql
create table grade_changes (
    enrollment_id integer,
    old_grade_id integer,
    new_grade_id integer,
    timestamp timestamp
);
```

Trigger Example: Trigger

```sql
create trigger grade_audit
after update
on enrollment
for each row
execute procedure grade_audit();
```

Trigger Syntax

```sql
CREATE TRIGGER name
{ BEFORE | AFTER } { event{ OR ... } }
ON table
{ FOR EACH { ROW | STATEMENT } }
EXECUTE PROCEDURE funcname( arguments);
```

DROP TRIGGER name ON table;

Triggering Events

- INSERT
- DELETE
- UPDATE

Before or After

- **BEFORE**: trigger fires before the triggering event
- **AFTER**: trigger fires after the event
Statement Trigger vs. Row Trigger

- **Statement Trigger**
  - Default
  - Fires once per statement

- **Row Trigger**
  - FOR EACH ROW
  - Fires once per row

---

Trigger Example: Function

```sql
create or replace function grade_audit()
returns trigger as $$
begin
  if new.id = old.id and new.grade_id <> old.grade_id then
    insert into grade_changes values (new.id, old.grade_id, new.grade_id, current_timestamp);
  end if;
return null;
end;
$$ language plpgsql;
```

---

About Trigger Functions

- No parameters
- Return type must be `trigger`
- Special variables
  - NEW, OLD
- Others:

---

Return Value of a Trigger Function

- Statement triggers and after-row triggers should return **NULL**
- Before-row trigger can return **NULL** to skip the operation on the current row
- For before-row insert and update triggers, the returned row becomes the row that will be inserted or will replace the row being updated

---

Examples: Enforce Data Integrity Constraints

- Create a trigger to enforce the constraint that the size of a Database class cannot exceed 30
  - RAISE EXCEPTION would abort the statement
